Give a drive link to the all CADs or text files you want to upload for problem 1.1 and problem 2 (either upload all of them in a folder and share the folder **or** upload a zip file and share the zip file)

https://drive.google.com/drive/folders/1c_4o8trDbcYPdDmre1gTPVZB_4hb6cmQ?usp=sharing

Give a drive link to 2-min max video running/explaining your work in problem 1.1

https://drive.google.com/file/d/19aYR01GIDVXb_2lZyha2g7blw3F2hKlZ/view?usp=sharing

Give a drive link to 2-min max video running/explaining your work in problem 2

https://drive.google.com/file/d/1Vtz7ie9vceKOCG7rVvQ_ATCPAa-QYbxX/view?usp=sharing

Answer for problem 1.2

Assuming the power supply is a SMPS with high efficiency and 5V output, the only power dissipated is through the current-limiting resistor and the LED

A red LED a forward voltage of 2.2V, therefore the current flowing in each LED ($i = (V_s - V_{led})/R = (5 - 2.2)/330 = 8.5 \text{ mA}$).

So the power in each "branch" is ($P = I^2 R + V_{led} I = (8.5 \times 10^{-3})^2 \times 330 + 2.2 \times (8.5 \times 10^{-3}) = 0.043 \text{ W}$

With a power budget of 1440W, the highest number of LEDs connected in parallel is $1440/0.043 = 33,488 \text{ LEDs}$.

Answer for problem 3

Since all required parts are 12 V, a 12V battery would be ideal for this application.

It should be able to continuously supply 16.5 Amps.

The required energy is $= (4 \times 12 \times 4 + 12 \times 0.5) \text{ W} \times (0.5) \text{ hr} = 99 \text{ Whr}$.

A 12 V battery should be at least $99/12 = 8250 \text{ mAh}$

Proposed Solution:

A (Li-ion) battery pack using 12 18650 high drain (3.7V, 3350mAh, 3C, 10A max., 50g)

batteries each 4 connected in series and 3 branches in parallel. The final battery pack would have the following specs:

14.8V, 148.74 Whr, 30A max., weighs 600g and would cost $90 \times 12 = 1080 \text{ EGP}$.

BONUS: Answer the questions that were proposed in Battery Basics session

Measuring Battery Capacity:

The battery should be fully charged and connected to a known load and have its power monitored continuously, either using a wattmeter or a combination of voltmeter and ammeter. The value of the energy delivered in each small time interval should be calculated $E = P \cdot t$, and the test should last till the battery's voltage is the minimum safe value.

The total capacity is then calculated as the sum $E_t = E_1 + E_2 + E_3 + \dots$

BONUS: Use your understanding of power and energy concepts to calculate your electricity consumption and its cost. Can you reduce it?

(refer to Battery Basics session)
